

ABSTRACT OF THE DISCLOSURE

An encoder suppresses effectively the high-frequency components of data to be transmitted by decreasing the
5 changing points of serial data, thereby suppressing EMI. A changing-point counter counts changing points of n -bit data (n : a positive integer) to generate a counting result, where values of adjoining bits change at each of the changing points. The changing-point counter outputting a discrimination bit
10 which is true when the counting result exceeds a predetermined value. A code converter converts the n -bit data in such a way that bits of the n -bit data located at predetermined positions are inverted when the discrimination bit is true. A parallel-to-serial converter converts $(n + 1)$ -bit data to a $(n + 1)$ -bit
15 serial code, the $(n + 1)$ -bit data being generated by adding the discrimination bit to an output of the code converter.
